Ignite R3.0
High-Level ST Test Plan and Strategy

Purpose

Check that the Digital Offer changes work as expected in System Testing (ST) before they are passed to the SIT teams. This plan covers OneApp Web, Android, iOS and the related Digital services.

How ST will be done

ST is **not an integrated environment**. Developers will create stubs (test responses that stand in for other systems) and configure them for the test cases. Where a connection to another system is needed, developers will provide the required stub instead of using the real integration.

The ST team will use these stubs to check the application behavior. Developers will provide different responses for offers, no offers, errors, delayed responses and successful or failed actions. Real connections and checks across systems will be handled by the SIT teams, not by ST.

What we will check

Offers: Offers display correctly using stub responses. The dashboard shows up to four offers, See All shows up to 20, and View All appears only when there are more than three offers. Offer text, images, order and unread count follow the agreed test setup.

Customer actions: Offer buttons, labels and destinations follow the stub response. Accept, dismiss and view actions give the expected screen changes. Cards and counts update only when the stub returns a successful action response.

Account and session changes: Switching accounts and signing in again use the correct stub data. Offers refresh after agreed completed actions, but not for scrolling or unfinished actions.

Fallback and settings: Check the agreed fallback display for no offers, errors and delayed responses. Do not mix fallback content with returned offers. Check source-selection settings using stubs only.

Events: Check through logs whether the expected accept, dismiss, view and impression events are triggered. Check that impressions are triggered only for visible offers, and repeated events follow the agreed rules.

Event checks using logs only

The ST team will perform an action and check the available logs in **Splunk, CloudWatch or another agreed logging tool** to confirm whether the expected event was triggered. Record the action, time and matching log entry as evidence. For actions that should not trigger an event, check that no matching event appears in the agreed observation period.

ST checks event triggering only. It does **not** check whether Pega or another system receives, stores or processes the event. A log entry confirms triggering only; it does not prove delivery. Those integration checks belong to the SIT teams.

If logs are unavailable or do not clearly show whether the event was triggered, record the test as blocked and ask developers to provide the required logging. Do not treat missing evidence as a pass.

Before testing starts

The test build, test cases and expected results must be ready. Developers must configure the required stubs and test data, explain how to select each response, and provide access to the logs. The ST team must be able to reset the test data and repeat the checks.

Agree any unclear screen behavior, event rules, waiting times and stub responses before testing the affected cases. ST uses the configured test setup; it does not certify real-system response times or performance.

Who does what

Developers: Build and configure the stubs, provide test data and logging, support testing and fix issues.

ST team: Prepare and run test cases, check screen behavior and event logs, record results, report issues and retest fixes.

Test lead and project owner: Agree the scope, review results and approve ST completion. **SIT teams:** Perform real integration checks, including event delivery and processing.

When ST is complete

Planned checks are completed and results are recorded. No Severity 1 or 2 issues remain open. Remaining Severity 3 or 4 issues must be less than 10% of all issues raised and accepted by the project owner. Any failed, blocked or untested cases must be clearly listed and reviewed before sign-off.

Share a short ST summary with the test results, log evidence, remaining issues and stub setup details. Clearly list checks that need real systems so the SIT teams can take them forward. ST completion does not mean integration testing is complete.
